“I don’t `git` it, why should I do this?”

- Version control – because you *will* screw something up.

“I don’t `git` it, why should I do this?”

- Version control – because you *will* screw something up.
- Version control – because uncontrolled version proliferation is *the devil*.

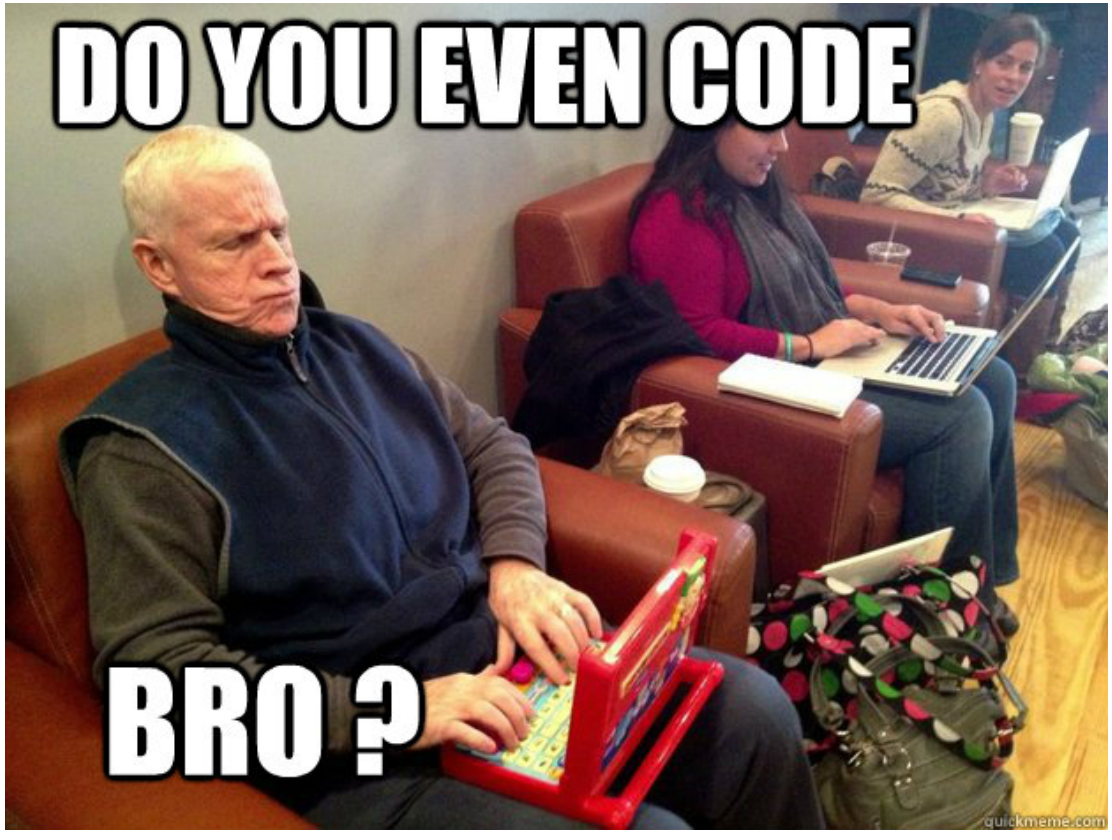
“I’m not really a coder”



You are, but even if you're "not"

Git made it possible for programmers to coordinate distributed work across teams -- now GitHub makes it possible for everyone else

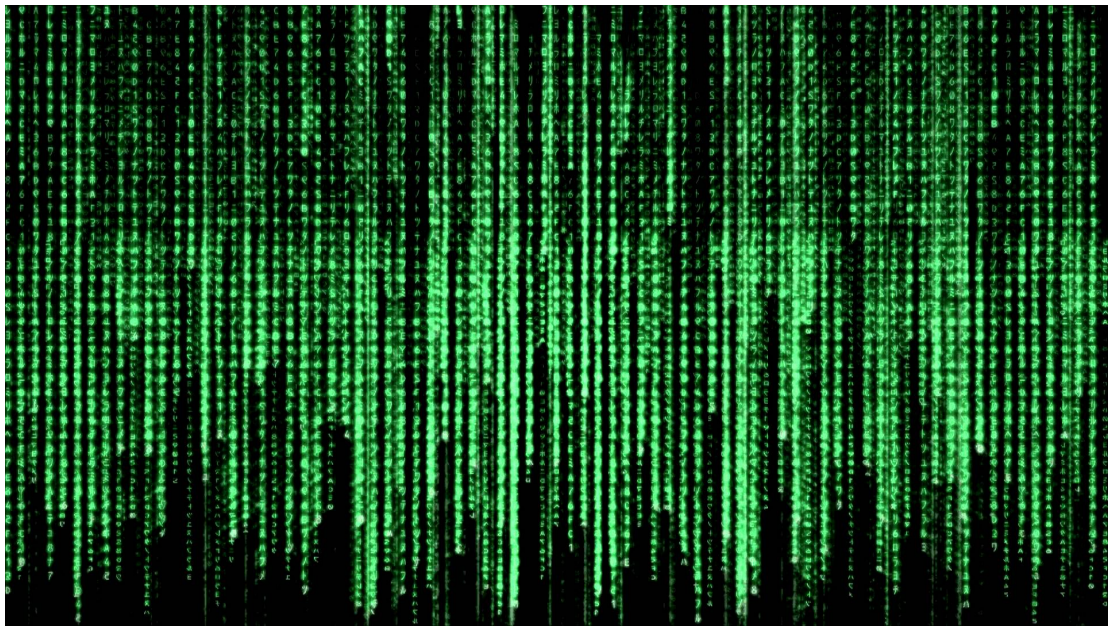
Working with a remote repository – `GitHub` (or `BitBucket`)

Let's make a GitHub log-in and repository!

Working with a local repository – `git`

Enter the matrix



Clone your new remote repo

```
git clone https://github.com/octocat/lovecatz.git
```

Now make some changes to your README.md on your computer, or create a new file. Perhaps `hello.cpp` if you're feeling real crazy.

Git used to it – the basics

You've made some local repo edits to some code, documentation, draft manuscript, data, or cookie recipe. What now?

```
#See what's changed
git status

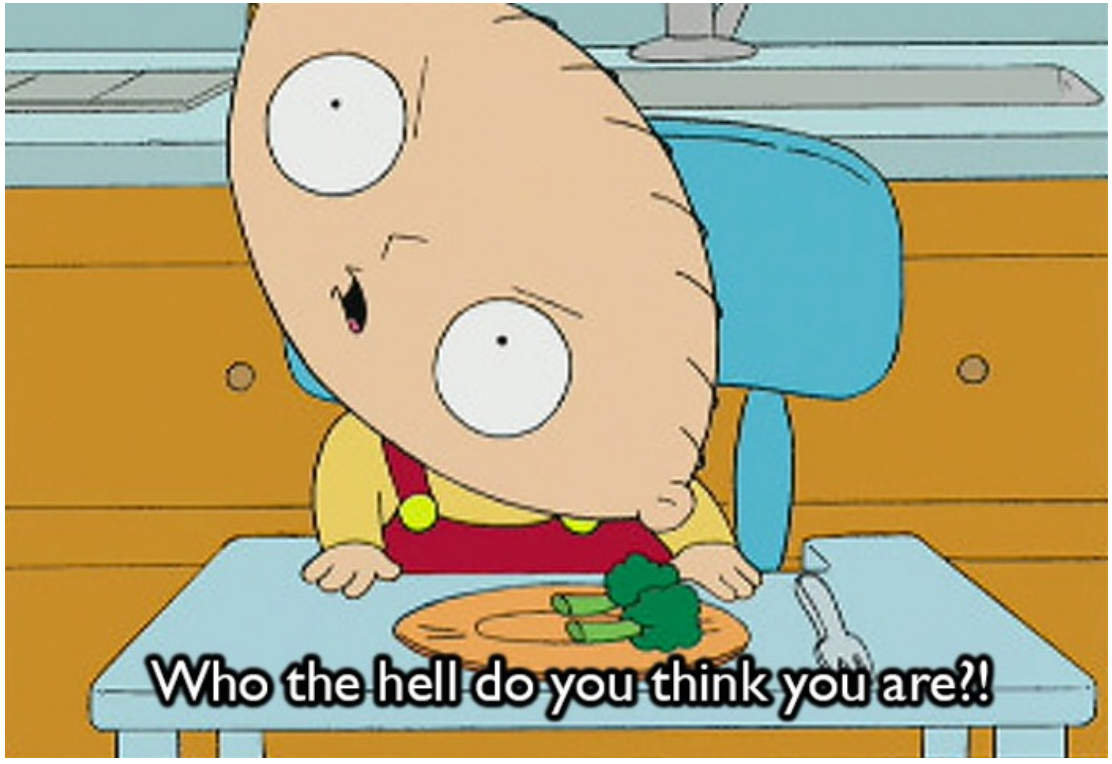
#prepare the content for the next commit -- "staging"
git add --all # --all, or specify files

#"The Rub" -- Record changes to the repository
#This is what creates version control
git commit -m "short discription of code changes"

#sync local and remote repos on master branch
git push -u origin master
```

Error!

```
git config --global user.name "Octocat69"
git config --global user.email "Octocat69@bbqchikn.com"
```



Back on track

```
#sync local and remote repos
git push -u origin master

#Up to date?
git status
```

Check out remote GitHub repo to see updates.

Practice the “add, commit, push” cycle 4X

add, commit, push
add, commit, push
add, commit, push
add, commit, push

Version control basics – reviewing file histories

```
#git overview of commits to repo
git log #for whole repo

#git overview of commits for one file
git log <filename>

#review int-th previous version of file
git show HEAD~<int>:<filename>
```

Explore previous commits – branch first!

Make a commit now just to be safe

```
#create a new branch
git checkout -b branch_name

#short term cache of current repo
git stash

#check which branch you're on
git branch #prints asterisk next to current branch

#go back to old commit by hash value
#see git log for hash values
git checkout <commit number>
```

What now?

1. If you were just curious, but like the most recent commits:

```
#go back to most recent commit
git stash apply
```

What now?

2. Or remove branch entirely

```
#remove branch name -- caution
git branch -d branch_name
```

What now?

3. Push your new branch to remote repo

```
git add --all # --all, or specify files
git commit -m "short discription of code changes"
git push -u origin branch_name
```

What now?

4. Merge with master branch,

```
#go back to master branch
git checkout master

#merge branch with master branch
git merge branch_name #read messages carefully!
```

What now?

5. Not your repo? Submit pull request. But – too much too soon.

Conclusions

- `git` and `GitHub` are valuable modern tools even for non-programmers – learn how to use them!

- You can now make a solo repo and implement add, commit, push cycles for version control and remote storage.

- `git` and `GitHub` are valuable modern tools even for non-programmers – learn how to use them!
- You can now make a solo repo and implement add, commit, push cycles for version control and remote storage.
- Hopefully you have a sense of the more advanced version control options available to you, even if you aren't comfortable using them yet.

Where to go from here

practice lots, read documentation, practice more
